Effect of ascorbic acid on activity of the adrenals during the alarm reaction. L. Borovic. *Acta Med. Yugoslavia* 5, 293-0 (1951); *Biol. Abstr.* 26, 2306 (1952).—Expts. on 18 rats indicated that ascorbic acid prevents hypertrophy of the adrenal glands in HCHO-exposed animals, but does not inhibit involution of the thymus. It is suggested that ascorbic acid in conditions of mild stress, though preventing hypertrophy of the adrenals, does not depress hypersecretion of corticosteroids, but may facilitate their synthesis in the adrenals.

Bodovac, Lj.

Muscular work and adrenocortical activity. Lj. Bodovac
and K. Kočival-Zivanović (Jugoslav. Acad. Sciences,
Zagreb, Yugoslavia). *Arch. Intern. physiol.* 50, 459-64.
(1952)(in English).—Female rats were made to run in a
treadmill 15-20 min. a day, and eosinophil counts were made
2 hrs. after the exercise. The counts were depressed 60%
of the prework values the 1st day but became progressively
less depressed as the animals became adapted to the muscular work. Significant depression was still seen on the 23rd
day. Similarly, adrenal ascorbic acid (I) (detd. on separate
animals) was reduced 30% after the 1st day's run, but the
decrease was progressively less on succeeding days. By
the 40th day there was no difference between pre- and post-
exercise I. Adrenal yr. was increased and total I increased
even faster, resulting in a true rise in I content. The secre-
tion of adrenocortical hormones increases at the beginning
of adaptation to heavy work, then returns to normal values.
C. D. Johnston

Reaction of eosinophils in rats adapted to adrenaline and histamine. Lj. Božović and L. Rabadžija. *Radovi. Med. fak. Zagreb* 1, 97-100(1953).—Rats treated with adrenaline and histamine show no decrease in the no. of eosinophils after 10 days. After adaptation to histamine rats reacted upon treatment with stressors, whereas rats treated with adrenaline were immune to other stressors and their eosinophil nos. remained unchanged. V. Mihailov.

Title : Stimulating the Hypophysis of Adrenalectomized Rats with
Adrenalin.

Orig Pub : Glasnik biol. sek. Hrvatsko prirodosl. drustvo, 1953 (1955),
Ser. 2B, 7, 104-105

Abstract : Adrenalectomized rats (AR) were intravenously injected
with adrenalin (I); 5 minutes later their hypophyses were
extracted in order that their ACTH [adrenocorticotropic
hormone] might be determined. It was found that hypophy-
ses of control rats contained 72 γ of ACTH, hypophyses of
AR which were given I injections, contained 120 γ of ACTH.
I increases the blood's ACTH content.

Adaptation to muscular work after a long period of rest.
L. Vassal L. Biotorev. J. L. Laroche (Ind. Ind.). [78]

[REDACTED] — In albino rats previously adapted to muscular work the decrease in number of eosinophiles and ascorbic acid content of the testes gland after exercise is less pronounced than in control animals, even after a resting period of one month. According to the eosinophil cell reaction and ascorbic acid test, the animals thus seem to remain adapted to muscular work in spite of the long rest. T. Bleau-Lister

"Tests of the Behavior of Enterotoxigenous Staphylococci During the Thermal Processing of Milk and the Preparation of Dairy Products."

Belgrade, Acta Veterinaria, Vol 13, No 1, 1963, pp 41-46.

Abstract: [Author's Serbocroatian summary modified] Raw milk originating in the vicinity of Belgrade often contains staphylococci, including those which enterotoxigenous. Differentiation and processing are discussed. A staphylococcal enterotoxin is created in raw milk held at a temperature of 23 degrees centigrade for 24 hours, in pasteurized milk for 12 hours, and in sterile milk for 10 hours. An enterotoxin once created cannot be destroyed by either renewed pasteurization or subsequent boiling for five minutes. A staphylococcal enterotoxin is also created in Sombor cheese, white cheese in hunks, and kajmak [similar to cottage cheese] at room temperature (approximately 22 degrees centigrade for three to six days and can be established even after 60 to 70 days. The staphylococci die out 50 to 60 days after the preparation of cheese and 50 days after the preparation of kajmak. The staphylococci create an enterotoxin within seven hours in an ice-cream mixture with starch at a temperature of 30 degrees centigrade, within eight hours if the mixture is without starch, and the enterotoxin does not die after the mixture is frozen. No references.

Title : Alkalimetric and Argentometric Determination of Sulfathio-carbamide.

Orig Pub : Acta pharmac. hung., 1957, 27, No.3, 119 - 124.

Abstract : An alkalimetric and argentometric method of sulfathiocarbamide ($n\text{-H}_2\text{NC}_6\text{H}_4\text{SO}_2\text{NHCSNH}_2$) (I) determination is proposed. Basic Blue B 6 is used as indicator at the titration with 0.1 n. NaOH in acetone solution; the maximum deviations are from +0.9 to -0.16%. The titration of tablets is carried out in an aqueous-acetone solution in the presence of Phenol Red, because Basic Blue B 6 is strongly adsorbed by the substratum contained in tablets, and Phenol Red is im-

pure aqueous solutions changes the tint in the region close to the same region of Basic Blue B 6. It produces a difficultly soluble compound ($n\text{-H}_2\text{NC}_6\text{H}_4\text{SO}_2\text{NHC}(\text{S}\text{Ag})=\text{NH}$) with Ag; the end of the titration with 0.01 n. AgNO_3 is determined with an ammeter; in order to avoid the formation of precipitate flakes, gelatin is added and an adjustment is made for the small absorption of Ag by gelatin. The maximum divergences at the argentometric I determination are from 1.03 to -0.31%.

Title : Determination of Lead Content in Lead Alloys

Orig Pub : Kohasz. lapok, 1955, 10, No 9, 423-424

Abstract : The known methods for determining Pb in alloys have been checked. The most extensively utilized molybdate method shows considerable discrepancies in the results; complete precipitation of $PbMoO_4$ takes place only at pH 8. Accuracy of Pb determination depends upon conditions of precipitation of PbS ; at pH 2 no precipitation of PbS takes place, at pH 2.5 it is contaminated by iron. Optimal pH value of the medium is 2-2.5. On the basis of this verification an accurate method has been developed for the determination of Pb. Prior to treatment with hydrogen

1320. Polarographic titrations with a rotating platinum electrode. III. The determination of antimony in alloys with potassium dichromate. I. Borzai (Rákos Márton Iron and Metal Works, Budapest, Magyar Nép. Poly., 1925, 61 (19) 563-568). - The method depends on oxidation of Sb^{III} to Sb^V with K₂Cr₂O₇, excess of which is titrated after 30 min. with Fe²⁺ soln. in a vol. of 100 ml in the presence of Kuop's soln. (H₃PO₄, id. 1.7, 150 ml + 0.1% S₂O₅, id. 1.5, 150 ml diluted to 1 liter, 170 ml) and conc. HCl (10 ml) until the diffusion current suddenly increases. A rotating platinum electrode kept at +1.0 V vs. the S.C.E. is used. If Ag is present, 1 per cent acacia mucilage (5 ml) is added before the HCl. Volumes of 20 to 50 ml containing 5 to 10 mg of Sb are used for the titration. Arsenic must be titrated previously as MgNH₄AsO₄. Antimony 1.5 µg in a vol. of 100 ml can be determined with an accuracy of ±6 per cent, but with 0.5 µg amounts the accuracy is of the order of ±1 per cent. The method can be used for the analysis of many common and rare metals, as well as their metalurgical by-products. A few mg per cent of Sb in copper alloys can be determined. A. G. Pazio

21. The use of amperometric titrations in the analysis of metals. (In German) L. Boesel. *Acta Chemica Scandinavica*. *Inorganica*. Vol. 9, 1956, No. 1-4, pp. 195-222, 20 figs., 10 tables.

The processes used in the practice of analyzing metals can be divided into direct redox titrations (determination of Cr, V, Mn and Fe), indirect redox titrations (determination of Sb, As, Bi, Te and Co), and precipitation titrations (determination of Ag, Zn and Cd). From the first group the determination of V, Cr, Cr₂O₇, V^{IV}, Mn and Co is dealt with in detail; from the second that of Sb, As, Bi and Te (which is accomplished by means of potassium dichromate), and from the third group the determination of Ag and Zn carried out by a precipitation reaction with KBr and K₂Fe(CN)₆. The rotating platinum electrode assembly used for the analysis is presented.

✓ 2095. New photometric method for the rapid determination of the lead content of steel. I. Borsig and E. Kopicsy (Rakosi Mátyás Iron and Metal-works, Budapest). *Magyar Kém. Foly.*, 19^o6, 82 (1), 12-15.—Dissolve steel-shavings (1 g) in H₂O (10 ml) and 60 per cent. HClO₄ (8 ml) with gentle warming, adding H₂O to keep the vol. constant. When solution is complete, add a few hundred mg of Pb-free steel-shavings (to remove Cu⁺⁺) and allow to stand for 3 min. Cool the soln., dilute it to 50 ml in a standard flask and filter. In a 10-ml graduated and stoppered test-tube, thoroughly mix conc. H₃PO₄ (5 ml), fresh gum acacia soln. (1 ml), prepared by dissolving 0.1 g of gum acacia in 6 ml of cold water) and the unknown soln. (2 ml). Dilute with water to 9 ml and, immediately before the determination, add 2.5 per cent. KI (1 ml); shake at once and determine the yellow PbI₂ against H₂O in a Pulfrich photometer, with a 1-cm cell and an S₂ filter. In practice, the extinction of a steel with a gravimetrically determined lead content is measured and this is used to calculate the Pb in the unknown. Otherwise the following formula can be used—mg of Pb per 10 ml of soln. = 0.18 × extinction, or percentage of Pb = 0.45 × extinction. The Pb-free steel must have an extinction <0.04. The accuracy is ± 0.02 per cent. The time required is 25 min. The metals usually present do not interfere, except for Cu⁺⁺, which is removed as described. A. G. PRO

2

Polarographic determination of small amounts of zinc in
the presence of large amounts of aluminum, János Barzai
(Institute Matéria Művek i.t.o., Budapest, Hungary)
Kém. Polgáriai 62/138-43 (1959) 47-50
The polarographic determination of Zn in the presence of a large amount of trivalent metal ions, e.g. Mg, Fe, or NH₄⁺, NH₄Cl solution, is not exact because of the adsorption of Zn²⁺. There is a great loss because of the adsorption in the presence of Al³⁺. To avoid the loss of the sample in the presence of Al³⁺, the stock solution must be added to the stock solution in 0.25N NH₄OH-NH₄Cl solution containing sulfosalicylic acid. The L₁ of the Zn strip is placed on the Hg surface which is in contact with the stock solution. Excess Mg does not interfere. In the presence of Al³⁺, the wave height decreases. Zn can therefore only be determined by the "addition method". To the unknown solution a known amount of Zn is added and the increase in wave height is measured. Oxygen is eliminated with cold Na₂SO₃ solution. The depression of the maximum 0.5% gelatin solution is 10%. This procedure is well suited for the determination of Zn in Mg-Al-Zn intermetallic Al₂O₃. Min. Zn content = 0.01%. Max. error is ± 1.5%.

44

2899. Polarographic titrations with a rotating platinum electrode / IV. Micro-determination of silver in copper alloy and soldering metals /
Borsig (Central Material Testing Dept. Iron and
Metal Works of Compt. Budapest). Magyar Kém.
Poly., 1956, 69 (11-12), 386-389.—Dissolve the

sample in conc. HNO_3 containing a little H_2SO_4 . To 20 ml of this soln. (containing not more than 5 mg. and preferably 1 to 2 mg. of Ag) add gum arabic (I) soln. (2%) (5 ml) and conc. HNO_3 (5 ml). and dilute to 100 ml with water. (The optimum vol. is 50 to 100 ml.) Add an excess of 0.01 N KBr and after 1 to 2 min. back-titrate with 0.01 N $AgNO_3$; polarise the rotating platinum electrode to + 0.05 V. The limit of determination is 1 mg of Ag in 50 ml; the accuracy then is within ± 0.5%. Higher concn. of HNO_3 or lower concn. of I decrease the accuracy. Even a 1000-fold excess of Cu does not interfere. Metals containing 0.1 to 95% of Ag can be determined. The direct titration of the HNO_3 soln. by means of 0.01 N HCl is less satisfactory.

Determining the lead content of free-cutting steels. I.
Parasai and K. Subbarao. *Kohinoor Letters* 10, 453-4
(1960) *Hung. Tech. Abstr.* 8, No. 2, Abstr. No. 79 (1960).
The gravimetric method has been modified so that detn. is
effected subsequent to sepn. with H₂S in the form of Pb
molybdate. The error from the incomplete sepn. of sul-
fide and molybdate can be eliminated by maintaining an
adequate pH. Optimal pH values are 2-2.5 for the sepn.
of PbS and 8 for that of Pb molybdate. Error of the modi-
fied method is $\pm 0.01\%$ Pb. R.J.C.
